Generating reports about pkgsrc

pkgsrcCon 2017

July 1-2 2017, London, United Exitdom

Pierre Pronchery
<khorben@NetBSD.org>
I am sorry...

- I could not complete the tool in time
- ...even less the talk
- It aims at generating reports about:
  - Currently known vulnerabilities (wiz@ does that too)
  - Packages by maintainer (so do bulk builds in a way)
- Do not miss http://repology.org though! (thanks wiedi@ for the hint)
That’s not all

- Instead I will go through what I have been presenting at AsiaBSDCon and BSDCan this year
- It is called “Hardening pkgsrc”
- It is about hardening pkgsrc
- I will be presenting it again at EuroBSDCon (world tour!!1)
Hardening pkgsrc

Securing packages, 17.000 at a time

pkgsrcCon 2017

July 1-2 2017, London, United Kingdom

Pierre Pronchery
<khorben@NetBSD.org>
About myself

• Pierre Pronchery, planet Earth
• DeforaOS Project since 2004
• IT-Security consultant since 2006
• NetBSD developer since May 2012
• Working on NetBSD with Git through the EdgeBSD community since August 2013
• Co-founder of Defora Networks since July 2016: https://www.defora.net/
Introduction

- pkgsrc is a multi-platform:
  - Software distribution
  - Build framework
  - Package manager

- Default source for packaged software on NetBSD, SmartOS, Minix...

- Supports many more!
  - Over 17,000 packages on 17+ platforms
Motivation

- As illustrated again in the news this week, a “cyber-war” is raging right now
- We have a responsibility towards our users
- pkgsrc offers a great opportunity for hardening a complete software setup
Agenda

1. Security management  
   Processes in place

2. Hardening features  
   Technical measures

3. Future work  
   Perspectives for improvement

Questions & Answers
1. Security management

1. Teams in charge
   - Security Team
   - Release Engineering Group

2. Vulnerability assessment database
   - Usage from source
   - Auditing binary packages

3. Maintenance of the stable release
   - Security patches
   - Long-Term Support (LTS)
pkgsrc Security Team

- List of duties:
  - Handles security issues relevant to pkgsrc:
    pkgsrc-security@NetBSD.org
    http://pkgsrc.org/pkgsrc-security_pgp_key.asc
  - Maintains the vulnerability database:
    http://cdn.netbsd.org/pub/NetBSD/packages/vulns/pkg-vulnerabilities.bz2
Vulnerability database

- Assembled from:
  - Release notes from upstream packages
  - Security Advisories from vendors (but *not* Secunia)
  - Announcements on public mailing-lists (OSS-Security...)
  - Erratas or advisories from other distributions, governmental or technical organisations (MITRE, CERT...)
- Cryptographically signed (PGP)
Vulnerability assessment

- Configure updates in `/etc/daily.conf`:
  `fetch_pkg_vulnerabilities=YES`

- To fetch manually:
  `# pkg_admin fetch-pkg-vulnerabilities -s`

- To audit the packages installed:
  `# pkg_admin audit`
Vulnerability assessment (from sources)

sysutils/xenkernel45$ make install
=> Bootstrap dependency digest>=20010302:
  found digest-20160304
===> Checking for vulnerabilities in xenkernel45-4.5.5nb1
Package xenkernel45-4.5.5nb1 has a information-leak vulnerability, see
http://xenbits.xen.org/xsa/advisory-200.html
[...]
ERROR: Define ALLOW_VULNERABLE_PACKAGES in
/etc/mk.conf or IGNORE_URL in pkg_install.conf(5) if
this package is absolutely essential.
*** Error code 1
Vulnerability assessment (binary packages)

# pkg_add wireshark-2.2.1.tgz
Package wireshark-2.2.1 has a denial-of-service vulnerability, see https://www.wireshark.org/security/wireshark-sec-2016-58.html

[...]
pkg_add: 1 package addition failed
Vulnerability assessment (binary packages)

- In `/etc/pkg_install.conf`:
  ```
  CHECK_VULNERABILITIES=always
  ```
- Alternatively, set to `interactive` to be prompted:
  ```
  [...]  
  Do you want to proceed with the installation of wireshark-2.2.1 [y/n]?
  n
  Cancelling installation
  pkg_add: 1 package addition failed
Security Team members

- Alistair G. Crooks <agc@>
- Daniel Horecki <morr@>
- Sevan Janiyan <sevan@>
- Thomas Klausner <wiz@>
- Tobias Nygren <tnn@>
- Ryo Onodera <ryoon@>
- Fredrik Pettai <pettai@>
- Jörg Sonnenberger <joerg@>
- Tim Zingelman <tez@>
Release Engineering Group

• List of duties:
  – Manage stable branches
    https://releng.netbsd.org/cgi-bin/req-pkgsrc.cgi
  – Process pullup requests
    Including security issues
    https://www.netbsd.org/developers/releng/pullups.html#pkgsrc-releng
  – Schedule freeze periods
    https://www.pkgsrc.org/is-a-freeze-on/
**Pullup Ticket List - NetBSD pkgsrc**

- Show all open tickets | Show all stalled tickets | Show all resolved tickets of this branch | Show all older resolved tickets

Click on a column header to sort by that column.
Click on a ticket number or ticket subject to see the full text of that ticket.
Click on any other field to show only tickets matching that field.

Stable releases

- Stable releases happening every quarter:
  - 2016Q4 no longer maintained
  - 2017Q1 latest stable
  - 2017Q2 frozen (HEAD)
- Joyent provides Long-Term Support (LTS)
  - joyent/feature/backports/20XXQ4
    https://github.com/joyent/pkgsrc
  - Focus on SmartOS
Release Engineering Group members

- Ryo Onodera <ryoon@>
- Fredrik Pettai <pettai@>
- Eric Schnoebelen <schnoebe@>
- Benny Siegert <bsiegert@>
- S.P. Zeidler <spz@>
2. Hardening features

1. Package signatures
2. Stack Smashing Protection (SSP)
3. Fortify
4. Stack check
5. PIE (for ASLR)
6. RELRO and BIND_NOW
Package signatures

• Support introduced initially in 2001:
  – Based on X.509 certificates or GnuPG
• Ensures authenticity and integrity:
  – Critical when installing binaries over HTTP or FTP
• Used by Joyent on SmartOS since 2014Q4:
  – Patch to use libnetpgpverify instead of GnuPG
• Still using GnuPG to generate packages
Package signatures

• Chicken and egg problem with GnuPG:
  – Not available in base
  – Needs to be installed as a package to verify itself

• Adding support for netpgp instead:
  – Available in NetBSD’s base system
  – Command line wrapper available (gpg2netpgp)
  – Still requires some patches (work in progress)
  – Security issue remaining with detached signatures
Package signatures (creation)

- Generate a key for the user building packages:
  $ gpg --gen-key

- In /etc/mk.conf:
  SIGN_PACKAGES=gpg

- Optionally, in /etc/pkg_install.conf:
  GPG=/usr/pkg/bin/gpg
  #GPG=/usr/local/bin/gpg2netpgp
  GPG_SIGN_AS=DEADBEEF

- Then use pkgsrc from source normally
Import the key for the user installing packages:
```bash
# gpg --import
```

In `/etc/pkg_install.conf`:
```
VERIFIED_INSTALLATION=always
```

Then use pkgsrc normally:
```bash
# pkg_add socat
```
```
gpg: Signature made Thu Nov  3 14:44:06 2016 CET
using RSA key ID CC245448
```
```
gpg: Good signature from "EdgeBSD test packages (khorben) <root@edgebsd.org>"
```
Primary key fingerprint: 968C 30DE B3C9 C147 203A 2E6E 5FFC 2014 CC24 5448
Stack Smashing Protection (SSP)

- Mitigation: reduce the impact and exploitation of Buffer Overflow vulnerabilities
- Different memory layout (stack variables)
- Addition of a « canary » value
  - Marker to detect memory corruption
  - Slight performance penalty
  - Controlled crashes instead of Code Execution
Stack Smashing Protection (SSP)

- Supported in pkgsrc for Linux (x86), FreeBSD (x86), and NetBSD
- Enabled in /etc/mk.conf: PKGSRC_USE_SSP=yes (or all or strong)
- Sets a compilation flag, in the case of GCC and clang: -fstack-protector (protects only some functions)
- Requires the package to support CFLAGS
  Some packages still do not 😞
Stack Smashing Protection (challenges)

• Only protects C/C++ programs and interpreters
  – JIT compilation is not protected
• Choose the adequate level of protection:
  -fstack-protector-all
    (protects every function)
  -fstack-protector-strong
    (balanced, but requires patch from Google)
• Add support for more compilers and platforms
Stack Smashing Protection (validation)

- To confirm a binary was successfully compiled with SSP:
  
  ```
  $ nm hello
  [...]  
  U __stack_chk_fail
  00600f00 B __stack_chk_guard
  
  This is specific to GCC on NetBSD
  ```

Fortify

- Automatically adds boundary checks: `sprintf()`, `strncat()`, `memmove()`...
- Completely mitigates some Buffer Overflows
- Involves support from the libc (system headers)
  - Negligible performance impact
  - Controlled crashes instead of memory corruption
Fortify

- Supported in pkgsrc for Linux and NetBSD (GCC)
- Enabled in `/etc/mk.conf`
  - `PKGSRCDCONF_USE_FORTIFY=yes` (or weak)
- Sets a pre-processing flag, in the case of GCC:
  - `-D_FORTIFY_SOURCE=2`
- Requires the package to support CFLAGS
  Just like SSP 😞
Fortify (challenges)

- Only protects C/C++ programs and interpreters
  - Again JIT compilation is not protected
  - Requires an optimization level of 1 or more (e.g. -O2)
- Choosing the adequate level of protection:
  - `D_FORTIFY_SOURCE=1` (weak, protects fewer cases)
  - `D_FORTIFY_SOURCE=2` (stronger but conforming programs might fail to build)
- Add support for more compilers and platforms
Fortify (validation)

- To confirm a binary was successfully compiled with Fortify:
  $ nm hello
  […]
  U __sprintf_chk

This is specific to GCC on NetBSD

- Enabled by default in Ubuntu Linux and Android
Stack check

• Generates code to verify the boundary of the stack
  *According to gcc(1): only really useful for multi-threaded code*

• Involves support from the compiler (GCC)

• Not in pkgsrc yet, but patch available in EdgeBSD

• Enabled in `/etc/mk.conf`:
  PKGSRC_USE_STACK_CHECK=yes

• Sets a compilation flag, in the case of GCC and clang:
  `-fstack-check`

• Also requires the package to support CFLAGS
Stack check (challenges)

- Determine support by other compilers (clang...)
- Apply for multi-threaded applications only? (how?)
- Validate if this mitigation is effectively in use
- Investigate if relevant by default
Position-Independent Executables (PIE)

- Necessary companion to PaX ASLR (Address Space Layout Randomization)
- PaX ASLR enabled by default in NetBSD 8 (incoming!)
- Allow compiled binaries to be re-positioned dynamically in memory
- Makes exploitation more difficult (requires a memory leak including pointer values)
- Involves compilation and linking phases
Position-Independent Executables

- Supported in pkgsrc for NetBSD and GCC
- Enabled in /etc/mk.conf:
  PKGSRC_MKPIE=yes
- Sets a compilation flag, in the case of GCC:
  -fPIC
- Requires the package to support both CFLAGS and LDFLAGS as well (with a caveat)
  Even stricter than SSP and Fortify 😞
Position-Independent Executables (challenges)

• The compilation flag should really be -fPIE for executables

• The linking phase must be completed with -pie but **only for executables so not directly through LDFLAGS**

• Currently implemented in the GCC wrapper

• **Not supported in cwrappers yet** (patch to be revisited)
Position-Independent Executables (advantages)

- Packages linked but not compiled correctly will **fail to build**
- Great way to know which packages do not implement flags as they should
- Program crashes usually reveal silent bugs
- Can be combined with `paxctl` otherwise: `NOT_PAX_ASRL_SAFE` `NOT_PAX_MPROTECT_SAFE` (expects filenames, see `mk/pax.mk` for more details)
Position-Independent Executables (validation)

- To confirm an executable binary is a PIE:
  
  ```
  $ file hello-pie
  ELF 64-bit LSB shared object, x86-64, version 1 (SYSV), dynamically linked (uses shared libs), for NetBSD 7.0, not stripped
  ```

  ```
  $ file hello-nopie
  ELF 64-bit LSB executable, x86-64, version 1 (SYSV), dynamically linked (uses shared libs), for NetBSD 7.0, not stripped
  ```
RELRO and BIND_NOW

- RELRO protects ELF executable programs from tampering with relocations at run-time
- Makes exploitation harder by reducing the attack surface through jump tables
- Benefits from immediate binding with BIND_NOW
- Performance penalty when starting big programs
- Involves the linking phase
RELRO and BIND_NOW

- Supported in pkgsrc for Linux and NetBSD (GCC)
- Enabled in /etc/mk.conf:
  PKGSRC_USE_RELRO=yes (or partial)
- Sets two linking flags, in the case of GCC:
  -Wl,-z,relro -Wl,-z,now
- Requires the package to support LDFLAGS
RELRO and BIND_NOW (challenges)

- Choosing the adequate level of protection:
  - Full, or
  - Partial (without BIND_NOW)
- Some packages break at run-time with full RELRO (e.g. dependency management for Xorg drivers)
- Could be adapted to more platforms
- Requires support from packages again 😞
RELRO and BIND_NOW (validation)

• To confirm a binary was built with RELRO and BIND_NOW:

```
$ objdump -x hello
[...]
Program Header: [...]
    RELRO off 0x00000d68
    vaddr 0x00600d68
    paddr 0x00600d68 align 2**0
    filesize 0x00000298
    memsz 0x00000298 flags r--

[...]
Dynamic Section: [...]
    BIND_NOW 0x00000000
```

• Patch available for PKG-devel checks
edgebsd/hardening

- Package meant to test a local pkgsrc setup:
  https://git.edgebsd.org/gitweb/?p=edgebsd.git;a=tree;f=hardening

$ hardening
[!] Hi! I am a library.
[!] Let's see if I am strong enough...
[+] built with -fPIC
[!] Bye! I am not a library anymore.
[!] Hi! I am an executable.
[+] built with -fPIC, good enough for full ASLR
[+] built with _FORTIFY_SOURCE 2, all good
[+] mmap() failed W|X, good
[-] mmap() gave two identical addresses :(
Demo

• Let us pray the demo gods?
• This presentation is the demo
• Userland with every feature mentioned so far (except Modular Xorg with partial RELRO)
• All the way to LibreOffice 5.3.0.3
3. Future work

- Reproducible Builds
- Code Flow Integrity (CFI)
- SafeStack
- Address Sanitizer
Reproducible Builds

« Reproducible builds are a set of software development practices that create a verifiable path from human readable source code to the binary code used by computers. »

• More at https://reproducible-builds.org/
Reproducible Builds

1. Deterministic build system:
   • Always the same result from a given source (including the current date and time, ordering of output...)

2. Pre-defined (or recorded) build environment:
   • Specific file format for build definitions

3. Let users reproduce and verify the original build
Reproducible Builds

- Already implemented in FreeBSD’s ports:
  - Initial patch takes the timestamp from distinfo
  - Specific patches needed as well (Perl...)
- Can affect many aspects of the build process:
  - Build environment: setting $SOURCE_DATE_EPOCH
  - Some flags relevant for GCC:
    - gcc -Wp,-iremap,...
    - gcc -fdebug-prefix-map=...
Code Flow Integrity (CFI)

• Prevents exploits from redirecting the execution flow of programs
• Controlled crashes instead of undefined behaviour
• Again, pkgsrc should be a great test-bed for this feature
Code Flow Integrity (Clang)

- Implementation available in Clang: http://clang.llvm.org/docs/ControlFlowIntegrity.html
- Requires the following in CFLAGS:
  -flto -fsanitize=cfi
  (individual schemes can be selected)
  and possibly -fvisibility=hidden
- Additional debugging information can be obtained
- Suitable for release builds:
  - Negligible performance impact
SafeStack (Clang)

- « An instrumentation pass that protects programs against attacks based on stack buffer overflows, without introducing any measurable performance overhead. It works by separating the program stack into two distinct regions: the safe stack and the unsafe stack. The safe stack stores return addresses, register spills, and local variables that are always accessed in a safe way, while the unsafe stack stores everything else. This separation ensures that buffer overflows on the unsafe stack cannot be used to overwrite anything on the safe stack. »
  https://clang.llvm.org/docs/SafeStack.html

- Involves CFLAGS:
  -fsanitize=safe-stack
Address Sanitizer (GCC)

- A memory error detector from GCC: https://gcc.gnu.org/onlinedocs/gcc/Instrumentation-Options.html
- Instruments memory access instructions
- Detects out-of-bounds and use-after-free bugs
- Involves CFLAGS: -fsanitize=address (more schemes are supported)
Closing words

- pkgsrc is a great project for testing security features
- Some possibilities can already be enabled
  could some of them be turned on by default?
- A lot more can still be done!
Call for action

• Turning some of these features on:
  – SSP (partial) and FORTIFY (full) in 2017Q3?
  – PIE in 2017Q4?
    (both are only applied where known supported)

• Packages signatures:
  – Default to netpgp ASAP

• Add more checks with PKG_DEVELOPER
Thank you!
